A screen for *S. cerevisiae* temperature-sensitive silencing mutants identified a strain with a point mutation in the *SIR2* gene. The mutation changed Ser276 to Cys. This amino acid is in the highly conserved NAD$^+$ binding pocket of the Sir2 family of proteins. Haploid strains of either mating type carrying the mutation were severely defective at mating at 37º but normal at 25º. Measurements of RNA from the *HMR* locus demonstrated that silencing was lost rapidly upon shifting the mutant from the low to the high temperature, but it took more than 8 hours to re-establish silencing after a shift back to 25º. Silencing at the rDNA locus was also temperature-sensitive. On the other hand, telomeric silencing was totally defective at both temperatures. Enzymatic activity of the recombinant wild type and mutant Sir2 protein was compared by three different assays. The mutant exhibited less deacetylase activity than the wild type protein at both 37º and 25º. Interestingly, the mutant had much more NAD$^+$-nicotinamide exchange activity than wild type, as did a mutation in the same region of the protein in the Sir2 homolog, Hst2. Thus, mutations in this region of the NAD$^+$ binding pocket of the protein are able to carry out cleavage of NAD$^+$ to nicotinamide but are defective at the subsequent deacetylation step of the reaction.
*S. cerevisiae* Sir2 protein is the founding member of a large family of NAD⁺-dependent deacetylases, the so-called sirtuins, conserved from bacteria to mammals (Frye 2000). These enzymes deacetylate lysines on proteins in an unusual reaction in which NAD⁺ is cleaved, if and only if acetyl lysine is in the active site of the enzyme, releasing nicotinamide and subsequently deacetylating the lysine to form a novel a compound, 2′-O-acetyl-ADP- ribose (Tanner et al. 2000; Tanny and Moazed 2001). Nicotinamide is a non-competitive inhibitor of these enzymes (Landry et al. 2000a). Several assays for sirtuins are available, including direct measurement of deacetylation, NAD⁺ hydrolysis during deacetylation, or NAD⁺-nicotinamide exchange (Landry and SternGlantz 2003). In the latter reaction, non-radioactive NAD⁺ is incubated with radioactive nicotinamide in the presence of enzyme and an acetylated substrate. Extent of the reaction is determined by the production of radioactive NAD⁺.

Yeast Sir2 is one of four so-called Silent Information Regulator proteins involved in transcriptional silencing of the silent mating type loci, *HML* and *HMR*, as well as genes near telomeres (Gasser and Cockell 2001; Rusche et al. 2003). It facilitates silencing by deacetylating histone H4 lysine 16, thereby forming a binding site for a Sir2, Sir3, Sir4 complex on nucleosomes (Rudner et al. 2005) Sir2 also is present in a different protein complex at the rDNA (Shou et al. 1999; Straight et al. 1999); its role within the rDNA array is to suppress recombination and silence RNA polymerase II transcription (Gottlieb and Esposito 1989; Smith and Boeke 1997), presumably by deacetylating lysines on histones.

Studies on establishment and maintenance of silencing at the *HM* loci have been aided by the use of a *sir3* temperature-sensitive mutation, *sir3*-8 (Lau et al. 2002;
MILLER and NASMYTH 1984). These studies have shown that inactivating Sir3 by raising
the temperature to 37º causes an immediate loss of silencing, whereas cells shifted from
37º to the permissive temperature, 25º, must pass through S phase and G2/M of the cell
cycle in order to re-establish silencing. A similar conclusion was reached by workers
who used special strains in which silencing was absolutely dependent on Sir1
(KIRCHMAIER and RINE 2001; Li et al. 2001). In those cases, re-establishment of
silencing by turning on expression of Sir1 also required passage through the cell cycle
and could not occur in cells held in G1. Interestingly, a recent study using a galactose-
regulated promoter to control Sir3 expression suggested that re-establishment of the fully
silent state required several generations (KATAN-KHAYKOVICH and STRUHL 2005). Here
we describe the identification of a sir2 temperature-sensitive (ts) point mutation that
changes a single highly conserved residue in the active site of the enzyme. We
characterize its effect on silencing at all four loci where it acts, and its enzymatic
properties in vitro.

MATERIALS AND METHODS

Strains and plasmids: Strains and plasmids used in this study are listed in Table
1 and Table 2, respectively. Strains used for the complementation test with strain TS1
were KN207, KN877, RS9 and KN9b. Yeast deletion mutants were constructed using
standard methods (LONGTINE et al. 1998). SIR2 and sir2-276 fragments, containing 300
bp both upstream and downstream of the open reading frame, were amplified from
genomic DNA of yeast strains RS1 and TS1, respectively, using primers CLP46 (5′-CCGCTCGAGTTTCTTTGACCCAAACGCCTT-3′) and CLP47 (5′-
CCGGAATTCATCTAGCACTCCTTCCAACCA-3’). Amplified products were digested with *EcoR*I and *Xho*I and cloned into the vector pRS316 (*URA3*, *CEN6*) to make pCLW18 and pCLW19, respectively. The same fragments were cloned into the vector pRS313 (*HIS3*, *CEN6*) to make pCLW21 and pCLW22, respectively. The entire *SIR2* and *sir2-276* coding regions were sequenced to confirm that there were no PCR-induced mutations. The GST-tagged *SIR2* *E. coli* expression plasmid, pDM111a, was obtained from D. Moazed (Tanny et al. 1999). A version of pDM111a with the *sir2*-276 mutation was made by amplifying DNA of yeast strain TS1 with primers CLP44 (5’-CCGGAATTCATGACCATCCCACATATG-3’ and CLP45 (5’-CCGCTCGAGTTAGAGGGTTTTGGGATG-3’). The amplified product was digested with *Cla*I and *Xho*I. The *Cla*I-*Xho*I fragment, which contains the *sir2*-276 mutation, was used to replace the *Cla*I-*Xho*I fragment of pDM111a to create pCLW20. The *HST2* *E. coli* expression plasmid pJWL03 was constructed as described (Landry et al. 2000b). hst2 R45A, H135A, Q115A and E128A mutant expression plasmids were made from pJWL03 with a site-directed mutagenesis kit (Stratagene) to create pJWL41, pJWL43, pJWL46 and pJWL47, respectively, as described (Min et al. 2001).

**Mating assays:** For patch mating assays, cells transformed with the indicated plasmids were patched onto the appropriate synthetic complete selective medium and grown at 25° or 37° for 1 day. Patches were transferred onto yeast-peptone-dextrose (YPD) medium by replica plating along with the appropriate mating tester strain (DC16 or DC17). After 6 hours, these cells were transferred by replica plating onto synthetic dextrose (SD) plates to select for diploids. Diploids were allowed to grow at 25° or 37° for 2 days. For quantitative mating assays, cells were grown in liquid YPD medium at
25° or 37° to exponential phase. Cell were diluted in YPD and plated onto YPD to count the total number of cells. Appropriate dilutions were also plated onto SD with 10⁷ cells of an exponentially growing mating tester strain (DC16 or DC17) at 25° or 37°. Mating efficiency was calculated as the fraction of cells that mated. All values are the means of data from three independent assays.

**Quantitative RNA measurements:** Cells were grown overnight in YPD and used to inoculate 30 ml of fresh YPD. Cells were then grown to an A₆₀₀~0.8, harvested, washed with diethyl pyrocarbonate-treated water and total RNA purified according to the protocol described by the Ambion Corp. Before cDNA synthesis, PCR controls were performed to confirm the absence of chromosomal DNA. To generate cDNA, 2 μg of total RNA was used in a 20 μl reaction with reverse transcriptase (Invitrogen). 2 μl of each cDNA reaction was amplified with a thermal cycler set of 94 °C for 4 minutes and then 23 cycles (for detection of α₁ or PMA₁ transcript in MATα strains) or 33 cycles (for detection of α₁ or PMA₁ transcript in MATα strains). α₁ transcript was detected from cDNA using primers as described previously (SMEAL *et al.* 1996). α₁ transcript was detected using CLP52 (5′-TCCAGATTCTGTTCCITTCTC-3′) and CLP53 (5′-CATTCTTCAGCGAGCAGAA-3′). *PMA₁* transcript was detected using PMA1-2018 (5′-CTATTATGTGCGTTTAAGACCTCCAG-3′) and PMA1-2290 (5′-TTATGGGGTATGTCTATTATTTTG GGCA-3′). PCR products were resolved on a 2% agarose gel stained with ethidium bromide. For radioactive PCR, the same amounts of cDNAs were analyzed by standard reaction mixtures to which 1μCi of [³²P]dATP (3 Ci/μmol) had been added. Products were resolved on a 2% agarose gel and quantified using a Storm840 scanner and ImageQuant software (Molecular Dynamics).
For temperature-shift experiments overnight cultures were grown at 25º or 37º for 2 hours and then shifted to 37º or 25º respectively. Cells were collected at different time points in 3 (25º to 37º shift) to 12 hours (37º to 25º shift) and total RNA isolated for RT-PCR by using primers that can specifically amplify HMR a1 transcripts. Primers that can amplify PMA1 transcripts were also used as a control. PCR products were resolved on a 2% agarose gel stained with ethidium bromide.

Silencing assays: Strains CCF100, RS2350 and RS2351 were used to measure telomeric silencing. Strains were grown in YPD for 1 day at 25º or 37º and then plated in five-fold serial dilutions on YPD medium and synthetic complete (SC) medium containing 0.1% 5-fluoroorotic acid (5-FOA). For rDNA silencing assays, strains RS2364 and RS2365 transformed with plasmids pCLW21 (SIR2), pCLW22 (sir2-276) or pRS313 (vector) were grown in SC-His-Leu medium at 25º or 37º for 1 day. Cells were spotted in fivefold serial dilutions on SC-His and SC-His-Leu + 5-FOA medium. Plates were incubated at 25º and 37º respectively for 2 to 4 days, depending on medium and temperatures.

Protein Expression in E. coli: Sir2 and Sir2 S276C were expressed in E. coli BL21(DE3) from pDM111a and pCLW20 after a 3-hour induction with 0.5 mM isopropyl β-D-thiogalactoside (IPTG) at room temperature. Proteins were purified using Glutathione Sepharose 4 Fast Flow Affinity Resin (Amersham) according to the manufacturer's instructions. Hst2 and mutants were expressed from pJWL03 (wild type), pJWL41 (R45A), pJWL43 (H135A), pJWL46 (Q115A) and pJWL47 (E128A) in E. coli BL21(DE3) and purified as described (LANDRY et al. 2000b). Purified proteins were dialyzed against 50 mM sodium phosphate (pH 7.2) and frozen at -80 ºC in 50 mM
sodium phosphate (pH 7.2), 0.5 mM DTT and 10% glycerol. Protein concentrations were estimated by comparing Coomassie brilliant blue staining of samples with BSA standards, analyzed by SDS/PAGE.

**NAD⁺ hydrolysis assays:** Reactions were carried out as described previously (LANDRY and STERNGLANZ 2003), using 50 μM H4 peptide or H4 lysine 16-acetylated peptide, 1 μCi [4-³H]NAD (0.37 Ci/mmol), and 50 - 150 ng purified Sir2 or Sir2 S276C. Reactions were incubated at 25° or 37° for 1 hour and terminated by adding 13.5 μl 0.5 M sodium borate (pH 8.0), and quenching on ice. Released nicotinamide was extracted by the addition of 0.5 ml of water-saturated ethyl acetate. After vortexing, samples were centrifuged at 16,000 x g for 2 min. 0.35 ml of the ethyl acetate fraction was transferred to 3 ml of Ecoscint scintillation fluid and the released nicotinamide quantified in a liquid scintillation counter.

**Deacetylation assays:** Reactions were carried out as previously described (LANDRY and STERNGLANZ 2003), using 50 μM H4 peptide or H4 lysine 16-acetylated peptide, 125 μM NAD, and 100 ng Sir2 or Sir2 S276C. Reactions were incubated at 25° or 37° for 1 hour and terminated by adding 13.5 μl 0.5 M sodium borate (pH 8.0), and quenching on ice. One μl of each reaction was spotted to a nitrocellulose membrane and histone deacetylation was detected by western blotting with an anti-histone H4 acetyl K16 antibody (Serotec).

**NAD⁺ - nicotinamide exchange assays:** Assays were performed as described previously (LANDRY and STERNGLANZ 2003) at 30° for 1 hr in 20 μl with 0.5 mM NAD⁺ (Sigma N-1511), enzymes (200 ng to 600 ng for Sir2 or Sir2 S276C; 1.3 ng for Hst2 mutants), 0.1 mM [¹⁴C]nicotinamide (Sigma N-2142, 53.1 mCi/mmol), 50 mM sodium
phosphate (pH 7.2), 0.5 mM DTT and 0.2 mg/ml chicken erythrocyte histones. After incubation, 8 µl of each reaction was spotted to Whatman HPKF Silica Gel 60 A thin layer chromatography plates. The plates were developed in a preequilibrated chamber with 80:20 ethanol:2.5 M ammonium acetate. After chromatography, the plates were air dried, sprayed with EN3HANCE (NEN NEF981) and exposed to film (Kodak X-Omat AR) at -80° for 24 hours.

RESULTS

Identification and characterization of a sir2 ts mutant: In order to identify temperature-sensitive (ts) silencing mutants, a yeast strain, RS1, with a TRP1 reporter gene at HMR was used (BRAND et al. 1985). This strain could not grow without tryptophan in the medium due to silencing of the TRP1 gene (a Trp⁻ phenotype). Spontaneous mutants were selected that were Trp⁺ at 37º but Trp⁻ at 25º. One such mutant, TS1, was analyzed further by crossing it with sir1, sir2, sir3 or sir4 mutants of opposite mating type (see Materials and Methods and Table 1 for a description of these strains). Analysis of the Trp phenotype of the resultant diploids demonstrated that the mutation in strain TS1 failed to complement the sir2 mutation and thus suggested the silencing defect in TS1 was due to a mutation in the SIR2 gene. Further evidence that the mutation was in the SIR2 gene came from analysis of a cross of strain TS1 with a nat1::LEU2 mutant (MULLEN et al. 1989). NAT1 and SIR2 are adjacent genes and therefore recombination between them should be extremely rare. Eleven tetrads resulting from this cross were analyzed. All were Parental; i.e., all the Leu⁻ segregants exhibited ts
mating and/or a ts Trp phenotype while none of the Leu+ segregants did. This
demonstrated that the ts silencing mutation was tightly linked to \textit{NATI} and thus
consistent with a \textit{sir2} mutation.

Therefore the \textit{SIR2} gene was amplified from strain TS1 by PCR and sequenced.
A single nucleotide change was found when the sequence was compared to that of the
parental wild-type strain. It was predicted to change Ser276 to Cys. The amplified \textit{SIR2}
fragment from both the mutant and the wild-type parent was cloned into a yeast shuttle
vector. The two resulting plasmids were transformed into \textit{sir2Δ} strains and mating of the
transformants tested. As seen in Figure 1A, mating is normal at both 25° and 37° for
wild-type \textit{SIR2} but is ts for the mutant. This demonstrates conclusively that the mutation
cauing the ts silencing defect is in \textit{SIR2}. We named this allele \textit{sir2-276}. The mutation
was also crossed into strains of both \textit{a} and \textit{α} mating type. Again mating of these strains
was seen to be ts, as judged by both patch mating (not shown) and quantitative mating
(Table 3). Note that mating was more than 10-fold worse at 37° in the \textit{MATα} strain than
in the \textit{MATα} strain, suggesting that silencing was more defective at \textit{HMR} than at \textit{HML}.
Quantitative RT-PCR was used to measure \textit{a1} RNA from \textit{HMR} in the \textit{MATα} strain and
\textit{α1} RNA from \textit{HML} in the \textit{MATα} strain (Figure 2A and B). This confirmed that the
mutation conferred a silencing defect and it was greater at \textit{HMR} than at \textit{HML}. The data
also showed that some RNA from \textit{HMR} was detected even at 25°, showing that the Sir2
protein from the mutant is somewhat defective even at a lower temperature.

The \textit{sir2-276} mutation was also introduced into a strain with a \textit{URA3} reporter
gene near a telomere. As can be seen in Figure 3A, the mutation led to a complete loss of
telomeric silencing at both 25° and 37°. To assess rDNA silencing, plasmids containing
either wild-type $SIR2$ or $sir2\!-\!276$ were transformed into two $sir2\Delta$ strains with a $URA3$ reporter gene in the rDNA array. The rDNA silencing of the transformants was then tested. As shown in Figure 3B, silencing at rDNA was normal at both 25° and 37° for wild-type $SIR2$ but was somewhat defective in the mutant at 37° for each of two strains tested. In summary, $sir2\!-\!276$ caused a temperature-sensitive silencing defect at both $HM$ loci and rDNA and a complete silencing defect at telomeres.

In order to determine if the mutant Sir2 protein was degraded at 37°, westerns were performed on extracts from cells grown at 25° and 37°. As seen in Figure 4, the mutant protein is present in amounts similar to that of the wild-type strain at both temperatures. Thus, the observed silencing defect of the mutant is due to loss of function of the mutant protein, not to its degradation.

**Temperature shifts:** Previous experiments with a $sir3$ ts mutant showed that mutant cells shifted from a low to a high temperature lost silencing rapidly while cells shifted from a high temperature to a low temperature required many hours and passage through the cell cycle to regain full silencing (Lau et al. 2002; Miller and Nasmyth 1984). We wanted to determine whether the same behavior would be seen with the $sir2\!-\!276$ mutant. As seen in Figure 5, when cells were shifted from 25° to 37° (top), silencing at $HMR$ was lost rapidly. On the other hand, when cells were shifted from 37° to 25° (Figure 5, bottom), it took more than 8 hours to see significant silencing of $HMR$. These results indicate that $sir2\!-\!276$, similar to $sir3\!-\!8$, also needs to pass through the cell cycle to re-establish complete silencing.

**Enzymatic assays:** The Ser276C mutation was introduced into a Sir2 plasmid used to express the recombinant protein in *E. coli*. Both the wild-type and mutant
recombinant proteins were purified using glutathione beads and then assayed for enzymatic activity. First, an H4 peptide acetylated on Lys16 was assayed by an NAD⁺ hydrolysis assay, commonly used to quantitate deacetylation by sirtuins (LANDRY and STERNGLANZ 2003). As seen in Figure 6A, the mutant protein had less activity than the wild-type protein at both 25° and 37° but retained some activity at both temperatures. Note that no activity for either protein was seen with an unacetylated H4 peptide, as expected. In another assay, deacetylation of the acetylated H4 peptide was measured directly by use of an antibody specific to H4 acetyl-Lys16. A western blot of the reactions demonstrated good NAD⁺-dependent deacetylation activity for the wild type protein but little or no activity for the mutant at both temperatures (Figure 6B). Next we assayed both proteins using a NAD⁺-nicotinamide exchange assay (LANDRY and STERNGLANZ 2003). A surprising result was obtained. The mutant reproducibly showed greater exchange activity than wild type (Figure 6C). The same proteins preparations were used in the two deacetylase assays described above as in this exchange assay. Since the mutant protein had less activity in both deacetylase assays, the greater NAD⁺-nicotinamide exchange activity seen for the mutant is a real effect and cannot be due to a higher concentration of functional mutant protein.

This result was reminiscent of an unpublished result we had obtained previously with a particular Hst2 mutant. As shown in Figure 7, an Hst2 Arg45Ala mutant also had greater exchange activity than wild type, whereas three other point mutants in conserved residues had lower activity than wild type. All four mutants tested had lower than wild type deacetylase activity (data not shown). The Arg45 residue of Hst2 corresponds to Arg275 of Sir2 and thus is right next to Ser276. Why mutations in this conserved region
of Sir2 have greater NAD⁺-nicotinamide exchange activity but less deacetylation activity will be discussed below.

DISCUSSION

As mentioned, sir2-276 was identified as a spontaneous mutation that led to a temperature-sensitive silencing defect at HMR. This mutation changes only one residue in Sir2, Ser276, to Cys. Interestingly, such a minor change of a side chain from -CH₂-OH to -CH₂-SH caused a significant enzymatic defect in vitro and significant silencing defects in vivo, showing the structural and enzymatic importance of Ser276 in Sir2. This amino acid is in a conserved disordered loop of the NAD⁺ binding pocket of the enzyme, termed the C site in the Sir2 superfamily (Min et al. 2001). The co-crystal structure of the yeast Sir2 homolog Hst2 with the product of NAD hydrolysis, 2’-O-Acetyl-ADP ribose (AAR), has been solved (Zhao et al. 2003). The structure indicates that Ser46, which is the homologous residue of Sir2 Ser276, is adjacent to Phe44 and Arg45 that form hydrogen bonds with the phosphate group of AAR. These results support the idea that Ser276 in Sir2 is important for its enzymatic activity as discussed below.

The Sir2 family of NAD⁺-dependent deacetylases acts in two steps (Jackson et al. 2003; Landry et al. 2000a; Sauve and Schramm 2003). In the first step, NAD is cleaved, releasing nicotinamide. This step is reversible in the presence of excess nicotinamide and makes the exchange reaction possible in vitro. In the second step, which is irreversible, the protein substrate is deacetylated, releasing AAR. In our enzymatic assays, we observed that Sir2 S276C protein is defective in deacetylation as determined by two assays, NAD hydrolysis and western blotting. In these two assays the
activities were measured by detecting the final products of the whole two-step reaction, nicotinamide or unacetylated lysine, respectively. In the NAD$^+$-nicotinamide exchange assay, which measures the reversible first step, both Sir2 S276C and Hst2 R45A mutant proteins showed more activity than wild type protein. We think this is because the S276C mutation and the adjacent mutation in Hst2 inhibit the second step but not the first. This increases the lifetime of an acetyl-lysine-ADP ribose 1′-O-alkylamidate intermediate and thus leads to increased NAD$^+$-nicotinamide exchange (DENU 2005).

Recently, Khan and Lewis determined kinetic parameters for several different hst2 mutants, including the R45A mutant we have used (Khan and Lewis 2006). They found that the R45A mutant had a very similar binding constant ($K_m$) as wild type for either NAD$^+$ or an acetylated lysine substrate but the rate constant ($k_{cat}$) was about 6 times slower than wild type. They therefore proposed, as we do, that the function of Arg45 in Hst2 was to stabilize the acetyl-lysine-ADP ribose intermediate formed between step one and step two of the reaction, supporting our hypothesis that the adjacent Arg and Ser residues in the conserved loop play an important role in the second step of the deacetylation reaction.

Two silencing assays, mating (Figure 1 and Table 3) and quantitative RNA measurements (Figure 2), both showed that the sir2-276 mutation had a greater silencing defect at HMR than at HML. This result was somewhat surprising. Generally mutations that do not completely abolish silencing, such as nat1/ard1 or sas2, abolish silencing at telomeres, weaken it at HML, and hardly affect HMR. In other words, silencing is considered strongest at HMR, perhaps because the HMR-E silencer is the only one of the
four *HM* silencers with binding sites for three proteins, ORC, Rap1 and Abf1. Thus, it is not clear why the sir2-276 mutant affects *HMR* more than *HML*.

Our *in vitro* enzymatic assays have shown that Sir2 S276C is equally defective at both 25º and 37º (Figure 6 and 7). On the other hand, the mutant exhibited a temperature-sensitive mating and silencing defect (Figures 1 and 2) and an rDNA silencing defect (Figure 3B). However, the mutant had a complete loss of telomeric silencing at both temperatures (Figure 3A). Moreover, in the quantitative RT-PCR assays, some RNA from *HMR* was detected even at 25º (Figure 2), showing that the mutant is somewhat defective at a lower temperature. It is not clear why *sir2-276* strain has a strong temperature-sensitive silencing defect at the *HM* loci and rDNA when the mutant protein is enzymatically defective even at a lower temperature. Apparently, more Sir2 activity is required *in vivo* at 37º than at 25º.

Holmes and colleagues recently described several *sir2* ts mutants generated by error-prone mutagenesis (HICKMAN et al. 2007; MATECIC et al. 2006). All but one of these mutants had multiple amino acid changes. Their mutants fell into two classes. One group had defects in deacetylase activity and the other had defects in binding to Sir4 (MATECIC et al. 2006). Similar to the *sir2-276* mutant described here, they found that the deacetylase-defective mutants lost silencing rapidly when raised to the non-permissive temperature. Another study in which silencing was reestablished by galactose induction of Sir3 showed that restoration of complete silencing of *HMR* took more than three generations (KATAN-KHAYKOVICH and STRUHL 2005). Similarly, we found that it took more than 8 hours after lowering the temperature of the *sir2* ts mutant to observe significant silencing of *HMR* (Figure 5), clearly more than one generation. It will be
interesting to study the cell-cycle dependence of silencing reestablishment at both silent loci with this mutant, and compare it with previous studies in which the controlled production of Sir3 or Sir1 was used to examine re-establishment of silencing as a function of the cell cycle.

ACKNOWLEDGMENTS

R.S. thanks Kim Nasmyth in whose lab this work was initiated many years ago. We thank Danesh Moazed for the Sir2 expression plasmid. This work was supported by National Institutes of Health grant GM28220.

FIGURE LEGENDS

FIGURE 1. The sir2-276 mutation confers a temperature-sensitive mating defect. The indicated strains were transformed with a plasmid expressing SIR2, a vector or a plasmid expressing sir2-276 (pCLW18, pRS316 and pCLW19 for the MATα sir2 strain, RS869; pCLW20, pRS313 and pCLW21 for the MATα sir2 strain, RS1717). Mating was measured at 25° or 37° as indicated.

FIGURE 2. The sir2-276 mutation has a temperature-sensitive silencing defect at the HM loci. Expression from the HM loci of SIR2, sir2Δ or sir2-276 strains was determined by RT-PCR. (A) cDNA derived from RNA from MATα strains (W303-1b, RS1717, RS2291) grown at either 25° or 37° was amplified with primers to a1 and PMA1. The a1/PMA1 ratios were calculated and shown relative to the value for the sir2Δ strain which was set to 1. (B) cDNA from MATα strains (W303-1a, RS869, RS2292) cultured at either 25° or 37° was amplified with primers to αl and PMA1. The α1/PMA1 ratios were calculated and shown as in (A).

FIGURE 3. The sir2-276 mutation confers a complete silencing defect at telomeres and a temperature-sensitive silencing defect at rDNA. (A) Telomeric silencing. Five-fold serial dilutions of overnight cultures grown in YPD medium of SIR2 (CCF100) and sir2-276 strains (RS2350 and RS2351) containing a URA3 reporter gene integrated near telomere VR were spotted onto YPD plates and 5-FOA plates at either 25° or 37°. Good growth on 5-FOA plates means good silencing. (B) rDNA silencing. Strains RS2364 and RS2365, both with a sir2Δ mutation and containing a URA3 reporter gene within the
rDNA, were transformed with a SIR2 plasmid, a plasmid expressing sir2-276 or vector. Transformed strains were grown overnight in SC–His-Leu medium at 25° or 37° and 5-fold serial dilutions spotted on selective medium without and with 5-FOA.

FIGURE 4. The Sir2-276 mutant protein is stable at 37°. A western with an antibody to Sir2 showed that similar amounts of Sir2 were present in wild-type cells and the sir2-276 mutant grown at 25° or at 37°. No signal was seen for a sir2Δ strain. An antibody to tubulin was used to show that similar amounts of total protein were present in all lanes.

FIGURE 5. Measurements of a1 mRNA from HMR after temperature shifts of MATα SIR2 and sir2-276 strains. Cells were grown at 25° for 2 hours and raised to 37° for 0, 1, 2 and 3 hours (top), or grown at 37° for 2 hours and dropped to 25° for 0, 2, 4, 8 and 12 hours (bottom). cDNAs collected at different time points were amplified with primers to a1 and PMA1 and RNA quantified as in Fig. 2.

FIGURE 6. Enzymatic assays with recombinant Sir2 and sir2 S276C. (A) NAD⁺ hydrolysis. Assays were performed by incubating enzyme (0 to 1.5 μl of Sir2 or sir2 S276C, 100 ng/μl), radioactive NAD⁺ labeled on the nicotinamide moiety, and H4 peptide (unacetylated or acetyl-K16) at 25° or 37° for 1 hour. Activity was determined by measuring the amount of [³H]nicotinamide released. The sir2 S276C mutant protein shows defective NAD⁺ hydrolysis activity at both temperatures. (B) Deacetylase assays. The assays were performed by incubating enzyme (100 ng of Sir2 or sir2 S276C), + or - NAD⁺, and H4 peptide (unacetylated or acetyl-K16) at 25° or 37° for 1 hour. The
reaction mixture was spotted onto paper and activity was determined by probing with an anti-H4 Acetyl-K16 antibody. Deacetylase activity is shown by a weaker response to the H4 Acetyl-K16 antibody. As in (A), sir2 S276C shows defective deacetylase activity at both temperatures. (C) NAD⁺-nicotinamide exchange assays. The assays were performed by incubating enzyme (2 to 6 μl of Sir2 or sir2 S276C, 100 ng/μl), NAD⁺, radioactive nicotinamide and chicken histones at 30º for 1 hour. Activity was determined by the amount of [¹⁴C]NAD⁺ formed. sir2 S276C protein shows enhanced NAD⁺-nicotinamide exchange activity compared with Sir2.

FIGURE 7. NAD⁺-nicotinamide exchange assays with Hst2 mutants. Recombinant wild type and mutant Hst2 proteins were assayed by NAD⁺-nicotinamide exchange assays. The assays were done by incubating 1.3 ng of enzyme, NAD⁺, radioactive nicotinamide and chicken histones (substrate, with or without) at 30º for 1 hour. The Q115A, H135A and E128A mutants show reduced exchange activity while the R45A mutant shows enhanced activity.
